### **Critical Care BC Connect Update - May 2023**

### Sedation / Delirium

### **Regular Haldol likely not saving lives**

In this nice multi-centre RCT out of Europe published in NEJM: <u>AID Trial</u> looked at Haldol for a mixed ICU population with delirium showed NO BENEFIT to TID haloperidol versus placebo.

Context: Prior Studies (HOPE-ICU & MIND-USA) showed that prophylactic and regular antipsychotics in predominately hypoactive delirium did not help patients. In this population with a mix between hypo and hyperactive, there was still no clinical benefit, but interesting signal of benefit?

Bottom line: use of haldol should be limited to HYPERactive delirium.

Summary Here

#### Mean No. of Days (95% CI, -1.2 to 7.0) P=0.22 75 60 35.8 (95% CI, 32.9 to 38.6) 45 **32.9** (95% CI, 29.9 to 35.8) 30 Raw 15 Haloperidol Placebo Death at 90 Days 100 Adjusted absolute difference, -6.9 percentage points (95% CI. -13.0 to -0.6) Percentage of Patients 80 Adjusted relative risk, 0.84 60 (95% CI, 0.72 to 0.98) 43.3 36.3 40 20 Haloperido Placebo Serious Adverse Reaction in ICU 10 Adjusted absolute difference, 0.4 percentage points (99% CI, -1.9 to 2.7)

Placebo (N=490)

0.5 ml

3 times daily

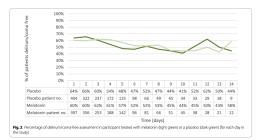

Days Alive and Out of the Hospital at 90 Days

Adjusted absolute difference, 2.9 days

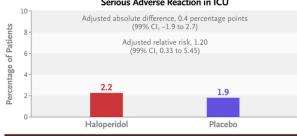

In this Australian multi-centre RCT, the <u>Pro-MEDIC</u> trial compared Prophylactic Melatonin to placebo for improvement sin daily delirium assessments. There was NO BENE-FIT to initiating enteral melatonin on admission to ICU.

Context: a prior <u>small single centre RCT</u> showed potential decrease LOS in ICU and improved sleep. This benefit was not demonstrated in this trial. LOS and sleep quality had no difference here.

Bottom line: Melatonin probably

does not belong on everyone's MAR / admission order-set <u>Summary Here</u>

#### CONCLUSIONS

Haloperidol

(N=510) 2.5 mg 3 times daily

90

Among patients with delirium in the ICU, the use of haloperidol did not lead to a longer time alive and out of the hospital than placebo.

### **Respiratory Support**

Table 3. Outcomes of Tracheal Intubation			
	Fluid bolus (n = 538)	No fluid bolus (n = 527)	Difference (95% CI) <sup>a</sup>
Primary outcome			
Cardiovascular collapse, No. (%) <sup>b</sup>	113 (21.0)	96 (18.2)	Absolute, 2.8 (-2.2 to 7.7)
New or increased receipt of vasopressors	111 (20.6)	93 (17.6)	Absolute, 3.0 (-1.9 to 7.9)
Systolic blood pressure <65 mm Hg <sup>c</sup>	(n = 535) 21 (3.9)	(n = 524) 22 (4.2)	Absolute, -0.3 (-2.8 to 2.3)
Cardiac arrest	9 (1.7)	8 (1.5)	Absolute, 0.2 (-1.5 to 1.8)
Death	4 (0.7)	3 (0.6)	Absolute, 0.2 (-1.0 to 1.3)
Secondary outcome			
In-hospital death prior to 28 d, No. (%)	218 (40.5)	223 (42.3)	Absolute, -1.8 (-7.9 to 4.3)
Exploratory procedural outcomes <sup>d</sup>			
Systolic blood pressure, median (IQR), mm Hg <sup>c</sup>			
Lowest level	116 (93 to 139)	113 (95 to 134)	Median, 3.0 (-3.0 to 7.0)
Change in level	-7 (-26 to 0)	-9 (-27 to 0)	Median, 2.0 (-2.0 to 5.0)
Lowest arterial oxygen saturation, median (IQR), mm Hg	96 (86 to 100)	96 (88 to 100)	Median, 0 (-2.0 to 1.0)
Oxygen saturation <80%, No. (%)	(n = 531) 79 (14.9)	(n = 518) 71 (13.7)	Absolute, 1.2 (-3.3 to 5.6)
Exploratory clinical outcomes, median (IQR)			
Invasive mechanical ventilation-free days through 28 $d^{\rm e}$	14 (0 to 25)	12 (0 to 25)	Median, 2.0 (-10.0 to 15.0)
Intensive care unit-free days through 28 d <sup>f</sup>	9 (0 to 22)	9 (0 to 22)	Median, -0.5 (-9.0 to 9.5)

### If you give a drug to drop SVR, Fluids won't help alone

In this follow up RCT, the <u>PRE-</u> <u>PARE II</u> trial published in JAMA explored fluid administration and peri intubation hypotension / cardiovascular collapse.

Context: Peri intubation is brought with cardiovascular collapse in our critically ill patients. The prior PREPARE 1 trial showed no benefit to fluid administration apart

from those patients getting positive pressure ventilation.

Bottom Line: I will continue to be using in line vasopressors for all critically ill intubations, as 1/5 patients will experience a SBP <65 or need higher doses of pressers, whether 500ml of crystalloid is given or not.

#### Summary here

### Aim for the mid-field in SPO2 targets for N/IMV Patients

In this single centre crossover RCT (Nashville <u>PILOT Trial</u>) there was no clinical benefit to low (88-92%) vs intermediate (92-96%) or vs high (96-100%) SPO2 targets.

Context: After the ICUROX challenged how we target O2 sats, this small but well done trial confirms the goldilocks principle, no need to go too low or too high until MEGA-ROX guides us more.

Bottom line: no need to set an aggressively low or high O2 target, I'll aim for the middle of the field (92-96%) Summary Here

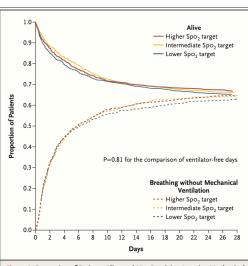

Figure 2. Proportion of Patients Alive and Not Receiving Invasive Mechanical Ventilation.

The proportion of patients who were alive and breathing without invasive mechanical ventilation during the 28 days after enrollment in each  $Sp_{0,2}$ . target group is shown. In a proportional-odds model, the number of days that patients were alive and free of invasive mechanical ventilation through day 28 did not differ significantly among the groups (P=0.81).

### IDSA in 2018 was right, Steroids in severe community Acquired Pneumonia

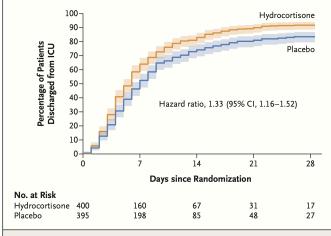

Figure 2. Discharge from ICU by Day 28.

Shown is the cumulative percentage of patients who were discharged from the ICU by day 28 (a secondary outcome in the trial). The length of ICU stay was compared in the framework of a competing-risk model, with death considered as a competing event. For secondary outcomes, the widths of the confidence intervals have not been adjusted for multiplicity and may not be used in place of hypothesis testing. In the <u>CAPE-COD</u> multi centre RCT published in NEJM, the early use of hydrocortisone (200mg administered over 24hr infusion) for 4 days lowered 28 day mortality in this admitted to ICU with severe CAP.

Context: Prior to the DEXA-ARDS trial, it was unclear who to administer steroids to with severe community acquired pneumonia. In the post covid era steroids are more readily administered, but over the past 25 years the evidence for the used of steroids in severe CAP was the ultimate pendulum.

Bottom line: Its appears for our CAP patients who are severely inflammatory phenotype (here a CRP >150) they would benefit from the administration of early steroids when admitted to ICU. <u>Summary Here</u>

Treatment failure

# BMI >35? Extubate to NIV

In this French multi centre RCT, the <u>EXTUB-OBESE</u> trial showed that extubation to NIV reduced the need for re-intubation / change of study therapy or stopping study therapy in obese critically ill patients.

Context: Although clinical guidelines and expert opinion still recommend extubation to NIV, some growing discussion around using

				failure (95% CI)	interaction
	NIV	Oxygen therapy			
Randomisation variable					
Type of oxygen therapy administered					0.50
Standard oxygen	31/245 (12.7%)	67/245 (27·4%)	H=1	0.29 (0.17-0.49)	
High-flow nasal oxygen	35/245 (14·3%)	63/246 (25.6%)		0.44 (0.27-0.73)	
Stratification variables					
Type of admission					0.38
Surgical	39/292 (13·4%)	70/293 (23·9%)		0.49 (0.32-0.76)

Overall	66/490 (13·5%)	130/491 (26-5%)		0.43 (0.31–0.60)	
				2	
			Favours NIV F	avours oxygen therapy	

Relative risk for treatment n value for

Figure 2: Subgroup analyses of the primary outcome

None of the prespecified characteristics, including length of mechanical ventilation, type of admission, or SARS-CoV-2 infection appeared to modify the effect of NIV group on the treatment failure rate. NIV=non-invasive ventilation.

HFNC for all extubations are creating into our practise.

Bottom Line: Our obese patients should be extubated to NIV and not other oxygen therapies alone.

## Deep sedation is harming our patients

In this mammoth of an international multi-centre observation trial, aka <u>WEAN SAFE</u>, a sobering result was that patients that are unable to wean from the ventilator quickly are likely to have a bad outcome. Sedation appears to be on low hanging fruit that can impact this patient population greatly. Factors of note: Frailty, Trauma, Use of NMBA, Mod/Deep sedation, increasing age, immunocompromised, cardiac arrest.

Interesting, only 65% of patients who are vented beyond 48hrs will be successfully weaned by 90 days post ventilation. Sedation seemed to prolong time to wean trial, as did lack of spent breathing trials.

#### Α Demographics Age (risk for every 10 years) Male sex Comorbiditie Obesity COPD Frailty Admission Type of admission (reference medical admission) Planned surgery Trauma Urgent surgery Cardiac arrest Non-traumatic neurological event Non-neurological SOFA score Management Use of continuous NMBA before WEC Level of consciousness (reference awake) Moderate sedation Deep sedation Intensive care unit with a written weaning protocol Geo-economic status (reference high-income Europe) Middle income Rest of the world high income в Demographics Age (risk for every 10 years) Male sex Comorbidities Immunocompromised Obesity Patient with chronic cardiac failure COPD Chronic kidney disease Frailty Admission Type of admission (reference medical admission) Planned surgery Trauma Urgent surgery Cardiac arrest Non-traumatic neurological event Pre-existing decision of limitation Non-neurological SOFA score Management Use of continuous NMBA before separation attempt Level of consciousness at separation attempt (reference awake) Moderate sedation Deep sedation Days from WEC to first separation attempt (for 1 day) Respiratory rate at first separation attempt (for 1 cm H,O) PEEP at first separation attempt (for 1 cm H,O) PIP minus PEEP at first separation attempt (for 1 cm H<sub>2</sub>O) Pa0, to FiO, ratio at first separation attempt (for 10 mHg) Pa0, to FiO, ratio at first separation attempt (for 10 mHg) Intensive care unit with a written weaning protocol Geo-economic status (reference high-income Europe) Middle income Rest of the world high income OR (95% CI)

Figure 4: Risk factors for weaning delays and weaning failure (A) Multilevel multivariable analyses showing the association between variables retained in the models and delayed initiation of weaning (ORs [95% CIs]). Blue dots and whiskers show variables significantly associated with lower risk of delayed initiation of weaning. Red dots and whiskers show variables associated with increased risk of delayed initiation of weaning. Black dots and hiskers show non-statistically significant ORs and 95% Cls. (B) Multilevel multivariable analyses showing the association between variables retained in the models and failed weaning. Blue dots and whiskers show variables significantly associated with lower risk of failed weaning (ORs [95% CIs]). Red dots and whiskers show variables associated with increased risk of failed weaning. Black dots and whiskers show nonstatistically significant ORs and 95% Cls. COPD=chronic obstructive pulmonary disease. NMBA=neuromuscular blocking agents. OR=odds ratio. PEEP=positive end-expiratory pressure. PIP=peak inspiratory pressure. SOFA=Sequential Organ Failure Assessment Pre-existing decision of limitation=decision to withhold or withdraw life sustaining treatments before intensive care unit admission. WEC=weaning eligibility

### Fluids

### Early vasopressors or less fluids in septic shock?

In the last year we saw both the CLOVERS and CLASSIC trials come out.

In the <u>CLOVERS trial</u> we see a multi-centre RCT of restrictive fluid (limit crystalloids, start vasopressors early) versus liberal fluid arm (bolus fluids before starting vasopressors). There was no difference in either group, apart from the fluid received (1.2L vs 3.8L in 24hrs).

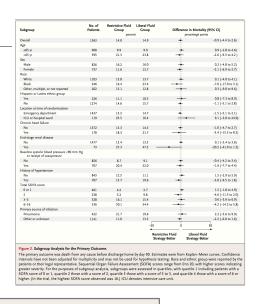

Table 3. Outcomes.*						
Outcome	Restrictive Fluid Group (N=782)			al Fluid Group (N=781)	Difference (95% CI)†	
	No. of Patients	Mean (95% CI)	No. of Patients	Mean (95% CI)		
Death before discharge home by day 90 — % of patients‡	782	14.0 (11.6 to 16.4)	781	14.9 (12.4 to 17.4)	–0.9 (–4.4 to 2.6)§	
No. of days free from organ-support therapy at 28 days	778	24.0 (23.4 to 24.6)	778	23.6 (23.0 to 24.3)	0.3 (-0.5 to 1.2)	
No. of days free from ventilator use at 28 days	773	23.4 (22.7 to 24.1)	771	22.8 (22.0 to 23.5)	0.6 (-0.4 to 1.6)	

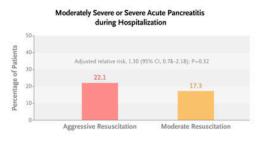

#### Summary Here

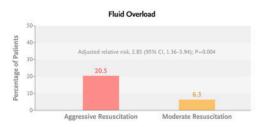

In the <u>CLASSIC trial</u>, a restricted fluid approach (1.8L) vs standard fluid (3.8L) showed no change in clinical outcomes of importance.

Table 3. Primary and Secondary Outcomes.							
Outcome	Restrictive-Fluid Group	Standard-Fluid Group	Adjusted Absolute Difference	Adjusted Relative Risk	P Value		
			percentage points				
Primary outcome*							
Death by day 90 — no./total no. (%)†	323/764 (42.3)	329/781 (42.1)	0.1 (95% CI, –4.7 to 4.9)	1.00 (95% CI, 0.89 to 1.13)	0.96		

It appears that after 15 years since PROMISE / ARISE / PROCESS, we are likely seeing multimodal resuscitative efforts tailored to our patients needs.

# We need to stop drowning our pancreatitis patients

20 years in the works, a group was finally able to perform the <u>WA-TERFALL Trial</u>. This multi centre RCT of aggressive (20ml /kg bolus w/ 3ml/kg/hr infusion) vs moderate (10ml/kg bolus w/ 1.5 ml/kg/hr infusion) of ringer's lactate resuscitation in pancreatitis patients. No big differences apart from fluid overload, but the trial was stopped early due to safety concerns by DSMB. <u>Summary here</u>

Table 2. Primary and Secondary Outcomes.*						
Outcome	Aggressive Fluid Resuscitation (N=122)	Moderate Fluid Resuscitation (N=127)	Relative Risk (95% CI)	Adjusted Relative Risk (95% CI)	No. of Patients with Missing Data†	
Primary outcome: moderately severe or severe pancreatitis — no. (%)‡	27 (22.1)	22 (17.3)	1.28 (0.77–2.12)	1.30 (0.78–2.18)	0	
Severe pancreatitis — no. (%)	8 (6.6)	2 (1.6)	4.16 (0.90-19.22)	2.69 (0.56-12.88)	0	
Local complications — no. (%)						
Any complication	25 (20.5)	21 (16.5)	1.24 (0.73-2.09)	1.28 (0.74-2.22)	0	
Necrotizing pancreatitis∬	17 (13.9)	9 (7.1)	1.97 (0.91-4.24)	1.95 (0.87-4.38)	0	
Infected necrotizing pancreatitis	5 (4.1)	3 (2.4)	1.74 (0.42–7.10)	1.45 (0.38–5.49)	0	

### Add acetazolamide to your diuresis regimes in CHF patients

In this multi-centre RCT, <u>ADVOR</u>, adding low dose acetazolamide (500mg daily) to standard loop diueresis resulted in faster time to decongestion and higher fluid negative levels obtained.

### **Common Interventions**

1. In <u>this nice RCT</u> clinical description in CHEST. Basically, a comparison of salvage epinephrine was equivalent to TXA in bleeding during bronchoscopy. TXA = Epi for bleeding after bronchoscopy.

2. In <u>this French multi-centre RCT</u>, stoping feeds then suctioning the stomach at the time of extubation was similar to 6 hrs of fasting. No need to holds feeds.

3. The <u>TEAM Trial</u> showed Early Active mobilization during IMV to be potentially HARMFUL <u>Summary Here</u>

4. The <u>EFFORT trial</u> showed high protein diet in critical illness should be avoided at least in AKI patients, and not needed for all patients. <u>Nice Summary here</u>

5. In this <u>wild multi-centre RCT</u>, patients with thrombocytopenia with counts 10,000- 50,000, likely need pre procedure transfusion IF YOU PLACE PREDOMINATELY SUBCLAVIAN LINES.
